Objective: The present study was carried out to assess gestational age in second and third trimesters with the help of ultrasonography measurements of one of the important fetal parameter, i.e., bi-parietal diameter (BPD) in local population (southern zone) of Rajasthan.

Methods: Two hundred normal pregnant females were studied with the known last menstrual period in southern part of Rajasthan. Gestational age was determined by measurement of fetal bi-parietal diameter with real time ultrasonography machine. Statistics was applied to correlate GA and BPD.

Results: In this study, foetal mean BPD showed linear increase from 13 to 36 weeks. Statistically significant correlation was found between GA and BPD (r = 0.38). Mean BPD showed increase of 2.38 cm in 13–20 weeks, 2.18 cm between 20 and 27 weeks and only 1.72 cm from 27 to 34 weeks. Average growth rate of BPD was found to be 0.31 cm/week from 13 to 28 weeks, which then later reduced to 0.23 cm/week from 28 to 36 weeks of gestation.

Conclusion: BPD is one of the useful criteria to measure GA and to predict expected date of delivery (EDD). Mean measurements of BPD in the present study were found to be lower than that of western studies except Hadlock series, which compares well with present study. The mean BPD values of present study compares well with some Indian studies and other found higher results. Variation in predicted values is attributed to anthropometric differences between the two populations due to racial, genetic, nutritional and socioeconomic factor. Therefore, large-scale studies should be done and population-specific tables should be derived to correlate BPD and GA.

35. Angle of femoral neck anteversion in Tamilnadu population of India

D. Ravichandran, K. Devi Sankar, P. Sharmila Bhanu

Karpagam Faculty of Medical Sciences and Research, Coimbatore, India

Background: Abnormal femoral neck anteversion (FNA) have been implicated in the etiogenesis of the hip osteoarthrosis and development dysplasia of the hip. The purpose of this study is to estimate the FNA in Tamilnadu population of India hitherto reported.

Method: Digital photographs of 187 dry adult femurs (right side – 75 and left side – 114) were taken and the angle of anteversion was determined with the aid of image tool software.

Results: The average angles of anteversion obtained were $18.5 \pm 9^{\circ}$ on right side and $19.4 \pm 11^{\circ}$ on the left side. Retroversion was observed in 3.17% femurs of both sides.

Conclusion: The knowledge of FNA angle nowadays is becoming more significant with the increase in demand for total hip replacement, and anthropological studies. The present study provides FNA data of Tamilnadu population, which adds to the other existing data and may be supportive for the interventional procedures undertaken in this population.

36. A morphological study of fetal myocardial bridges

<u>S.D. Nalina Kumari</u>, T.S. Gugapriya, E. Kamala, N. Vinay Kumar

Chennai Medical College Hospital and Research Centre, Trichy, Tamilnadu, India

Objective: A band is overlying the intramural segment of coronary artery – a place where the artery goes through myocardium instead of epicardium is myocardial bridging (MB). In adult cadaveric and angiographic study, a wide variation of 0.5–90.4% occurs in the incidence of MB with very little data on fetus. Hence, the aim of this study was to identify the presence of myocardial bridges in fetuses of varying gestational age.

Methods: Thirty fetal cadaveric hearts were examined. After removing epicardium, the course of the coronary arteries was delineated and observed for the presence of MB. In the hearts with MB, the location, length, and its distance from the coronary ostium were measured. Histological study of the artery under the myocardial bridges was done.

Result: Out of thirty hearts, 19 showed MB in the left anterior interventricular artery. Five and two hearts showed myocardial bridges in right coronary artery and circumflex artery, respectively. Multiple MB in single artery was seen rarely. The length of the MB segment was around 4 mm on an average. Mostly the MB is seen in the mid- to distal part of the artery. Routine H&E staining of the artery showed narrowing of the segment under MB.

Conclusion: This study concludes that MB is present in fetuses mostly in the left coronary artery. This study may provide potentially useful information for the preoperative evaluation of a newborn and may have clinical implication for sudden fetal deaths.

37. The role of Q-angle in the diagnosis of patello femoral pain syndrome

Umapathy Sembian, M. Muhil, Nandha Kumar

Dept. of Anatomy, Chennai Medical College Hospital & Research Centre (SRM), Trichy, Tamilnadu, India

Introduction: One of the most common disorders of knee is patella femoral pain syndrome (PFPS), which constitutes about 25% of all knee injuries treated in the orthopedic department. PFPS is considered to be a challenging problem to the clinicians, as multiple factors contribute to its etiology like abnormal lower limb mechanics, muscle weakness, soft tissue tightness and even over exercise. Till date, there is no gold standard test, which would pin point the diagnosis of PFPS. The most commonly used tests are (1) patellar tilt test, (2) palpation of patellar retinaculum, (3) patellar mobility test, (4) medio lateral glide, (5) patellar apprehension test, (6) muscle flexibility, (7) crepitus, (8) patellar tracking test, (9) patellar compression test, and (10) Q-angle. Among the above-mentioned test, an increased Q-angle with subsequent abnormal lateral tracking of patella is considered to be one of the main causes of PFPS.
